The program I have come up with is along the lines of a library of games that can help someone find a game they want to look into if they want to. Sometimes a person has no idea what they are looking for, so they may want to look into a specific genre or game type. For example, horror players might find something like Rootrot, or Fps player Far Far West. This is to help people find the games that they would want to play. It's a tool to help find the game, so they need to give it a genre that they want to look into if they want single- or multiplayer games.

Each item has multiple tags. It can run the same multiple times for different tags and have multiple tags to narrow it down even further. The reference is what the class shapes. For example, if a game has platformer and collaectathon as genres, then it will pull games like A Hat in Time. The class will compare the assigned data and pull.

I will have a defined list of games; while I can't include everything, it will need to be large enough that there are multiple items in it that can be pulled for any given genre selection.

Another key point is that it will need to be a form of search. And a smart Idea I have is to use Bucket search, where I can narrow it down. For example, assign a genre to a number; for example, 3 is horror, and 8 is platformer. I can't include every genre, but I can include a good set that can work together. And a bit of googling shows that I can have it pull numbers from a specific bucket. And to further narrow it down through recursion, I can use a second number to have a second genre be pulled as well

I also will have, so if they know exactly what they are looking for, they could just use something akin to an item number or a name of a game on the list.
